

Innovative perovskite technology paves way for greener optoelectronics

(Nanowerk News) Researchers at the Institute for Advanced Materials at the Universitat Jaume I in Castelló have created a method for synthesising organic-inorganic tin halide perovskites and generating thin films or coatings from them, which, when deposited on substrates, have optoelectronic properties that are useful for the creation of devices such as perovskite-based LEDs (PeLEDs).

The method developed by the team consisting of Dr Samrat Das Adhikari and the doctoral student, Jesús A. Sánchez Díaz, and led by the researcher Iván Mora Seró, exhibits excellent photoluminescence and stability properties that are suitable for commercial application in the field of optoelectronic devices (solar cells, LEDs, etc.).

It has been validated experimentally in the laboratory and is protected by a patent, ready for development and adaptation for particular applications through agreements.

The invention is part of the European project [DROP-IT](#) of the H2020 programme (Future and Emerging Technologies), led by the University of Valencia, which ends this year.

As explained by Iván Mora Seró at the beginning of the project, "The aim is to study materials such as halide perovskites, but which are lead-free and therefore less toxic, in order to create all kinds of electronic devices that can be printed on flexible substrates, such as LEDs, photodectors or other optoelectronic devices".

The teams led by Beatriz Julián and Víctor Sans also participated in the project.
